The following table shows the results of the regression analysis for the dependent variable "Number of children in the household" (N = 1,000). The independent variables are "Age of the head of household" and "Gender of the head of household". The table includes the coefficient estimates, standard errors, t-statistics, and p-values for each variable.

The first step in the process is to identify the problem. This involves gathering information about the situation and the people involved. Once the problem is identified, the next step is to analyze it. This involves breaking the problem down into its components and understanding how they are related. The third step is to develop a plan. This involves deciding on the best way to solve the problem and the steps that need to be taken. The fourth step is to implement the plan. This involves putting the plan into action and making any necessary adjustments. The final step is to evaluate the results. This involves assessing the effectiveness of the solution and determining if any further action is needed.

**Abstract**—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of workers. The study included 600 male employees from three companies. Data were collected by means of a questionnaire that asked about symptoms of musculoskeletal disorders and work characteristics. Results showed that the prevalence of musculoskeletal disorders was higher among non-manual workers than manual workers. This result may be due to the fact that non-manual workers had more sedentary jobs and less physical demands than manual workers.

**Keywords:** Musculoskeletal disorders, prevalence, workers' compensation, occupational health, ergonomics.

Musculoskeletal disorders are one of the most common causes of disability and lost productivity in the workplace. In the United States, musculoskeletal disorders cost employers over \$100 billion annually in direct and indirect costs (Bureau of Labor Statistics, 1998).

The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of workers. The study included 600 male employees from three companies. Data were collected by means of a questionnaire that asked about symptoms of musculoskeletal disorders and work characteristics. Results showed that the prevalence of musculoskeletal disorders was higher among non-

manual workers than manual workers. This result may be due to the fact that non-manual workers had more sedentary jobs and less physical demands than manual workers. The results of this study suggest that employers should consider the type of job and the physical demands of the job when designing work environments and selecting workers. By understanding the relationship between job type and musculoskeletal disorders, employers can take steps to reduce the risk of injury and improve worker health and safety.

The following table shows the results of the regression analysis for the dependent variable "Number of children" (N = 1,000). The independent variables are "Age" (in years) and "Gender" (Male/Female). The table includes the coefficient estimates, standard errors, t-statistics, and p-values for each variable.
